Experience

System Software Architect, NVIDIA [2010 Sep ~ Present]

- Role involves leading cross functional efforts between CUDA/Graphics/hardware and OS software teams. Also involves hands on coding in individual projects.
- **Page Table Coherence (Project Orion)**
  - Goal is to provide uniform address space between Denver(NVIDIA owned) CPU and GPU
  - My role is to scope out hw changes and drive Linux kernel VM changes.
  - Implementing asynchronous fault handling in the Linux kernel for faults originating from GPU. Uses worker threads and use_mm interface to switch in appropriate context for fault handling.
  - Also includes modifying PTE_DIRTY macros to look up GPU PTEs during page eviction. set_pte_at/tlb_flush routines modified to do remote GPU TLB shootdowns.
  - Driving GPU TLB hw changes required to improve invalidation latencies.
- **Tegra T40 Memory Consistency Models**
  - Scoping out changes required in SW stack to implement Weak Consistency Model between Cortex A15 ARM CPU and Kepler GPU without explicit CPU/GPU L2 cache coherence.
  - Running experiments to evaluate if flushes/invalidates provide sufficient performance or if lack of GPU/CPU cache line coherence is a product killer.
- **CUDA Page Based Memory Coherence (Upcoming Maxwell Architecture)**
  - Goal is to allow CUDA programs to pass pointers between CPU/GPUs using SW Page Based Cache Coherence and a weak memory model.
  - My role is to scope out GPU changes and Linux kernel VM changes for Page Base DSM.
  - Implemented proof of concept using MOESI in software to track page ownership.
  - Investigating ways to reduce false sharing. Studying real life app, memory traffic patterns.

Senior System Software Engineer, NVIDIA [2008 Sep ~ 2010 Aug]

- **Fermi Architecture Chip Lead (Resource Manager Team)**
  - Lead the overall technical efforts for Fermi Generation GPUs for the Resource Manager Team (OS Team) from **functional simulation through RTL/emulation all the way to Silicon bringup**
  - The role involved interacting with CUDA/OpenGL/DirectX and hw teams and driving technical implementation details for the Resource Manager team.
  - Also involved debugging very cross functional GPU hangs/bugs. Being familiar with 75% of the Fermi GPU, found myself become an ace debugger.
- **Improve Verification of Asynchronous Concurrent Code**
  - Implemented Probe Based Verification. Probes start up being noops in ISR code but can be dynamically modified at runtime to make it wait for certain events and thereby control order in which ISR sees certain events. Allows deterministically hitting/testing boundary conditions.
- **Vista Non stall interrupts and Lockless ISR**
  - Worked closely with hw to design new interrupt tree for handling non stalling edge triggered interrupts. Rewrote a separate ISR that has minimal data dependency on the main ISR and rest of driver. Path uses extremely fine grained spin locks and lockless data structures
- **Self Modifying Code Support**
  - Implemented API for OpenGL/CUDA/DX clients to use to modify their instruction stream after it has been queued in the GPU without introducing massive stalls. Under the hood this injects noops and acquire/releases and pipelined waits in the method stream before blitting in new code.

- **Windows 8 Mid Buffer Preemption** The goal here is to allow modification/reordering queued work and be able to inject new work with minimal latencies. Useful for desktop interactivity. My contribution was to provide APIs for Vista driver teams to use that allow submitted but not yet executed buffers to be reordered. Leverages Self Modifying Code Support from above.

System Software Engineer, NVIDIA [2006 Sep ~ 2008 Aug]

Software Component Lead (Fermi Thread Scheduling) Lead GPU Thread Scheduling Unit (Host) changes in Fermi from software. Work involved closely interacting with OpenGL/CUDA/DirectX and HW teams to identify perf hotspots, pitfalls from previous generations and drive changes with HW and implement/support them in the Resource Manager driver code.

- **Support Multiple PBDMAs** Previous architectures had a single instruction fetch/decode/feed to engine pipeline called PBDMA. This was unable to saturate PCIe bandwidth or keep GPU engines busy. My role here was to identify hotspots and work closely with hw to identify correct number of PBDMAs to fix above problems. Implemented SW support to split/ schedule instruction streams across PBDMAs and tweak timeslicing based on work load pattern.
- **Support Buffered Mode Scheduling** Based on discussions with SW teams and HW, drove efforts to implement a new scheduling mode tuned for Vista WDDM. This allows OS to queue work on various engines in order without explicit synchronization. Implemented this queue called runlist, added efficient notifier support. Added support code in RM for new mode.
- **Fix Perf Problems in Buffered Mode** Even though work is queued upfront by OS initial simulation showed hw was not taking advantage of this with better pipelining/prefetching. Worked with HW to add hints in RM to enable better prefetching / cache warming.
- **Optimize Runlist Data Structure** Runlist is the SW queue that contains schedulable work items where CPU produces GPU consumes. Split global runqueue into multiple per node queues to avoid concurrency problems between Compute / Graphics and Copy Engines. Implemented double buffering to allow CPU to modify runlist without stopping GPU. Implemented an indexed bitmap for the data structure to get better CPU cache locality.
- **Efficient Software Method Handling** Software methods (traps) allow pipelined execution of CPU code with GPU code. Implemented this handling to allow a bulk processing of sw methods from a single interrupt to reduce interrupt latency. Also added code for out or order SW method execution when SW methods are interleaved with hw methods.
- **Power Aware Scheduling (ELPG)** This existing feature allows engines to power down during bursts of inactivity. My role here was to port this code to the new scheduler and make sure stop scheduling and revive scheduling of power gated engines worked correctly. This feature was later staffed by an entire team and moved to microcode, helped them in this process.
- **Fault Recovery** Worked closely with the hw team to design SW for recovery from page faults engine hangs and other conditions and identify changes required for new scheduling modes. Actual implementation was done by other members in my team.
- **Pipelined Page/Resource Swapping** Worked with DX/HW to implement resource stealing from contexts that are not currently resident on the GPU and restoring them back right before they get to run. My contribution was injecting surrender resource / reclaim resource methods in existing instruction streams.

System Software Engineer, NVIDIA [2005 June ~ 2006 Aug]

<Joined the Resource Manager Team which implements the OS that manages the GPU. Its implemented partly in the host OS driver and parltly in microcode sitting inside the GPU>

- **G72 TurboCache** Helped the mmu component lead make changes in the Heap code to route surfaces to system memory. This was for a low end chip without local memory.

- Debugged and fixed bugs in MMU/Thread Scheduling/Power Management code. Did bringup.
- **Fermi NOMMU Support** Modified heap to allow physical and virtual addresses to match. This is very useful for debugging a new MMU hw.
- **Fermi MMU Page Table Support** Implemented initial code to support two level GPU page table. Added code to support single PDE pointing to two valid page tables. This was for Vista sysmem video memory swapping support.
- **Fermi MMU GPU TLB Invalidate** Wired up the TLB invalidate code. Optimized virtual address allocators to allow adjacent addresses to better utilize TLB using hints in PTE. HW had TLB coalesce/compress feature that aligned with this SW change.
- **GPU TLB invalidate Optimizations** Added code to batch invalidates to better use range based invalidation.
- **Fermi MMU NOINVALDATE mode** Modified allocators to skip TLB invalidates and L2 flushes entirely by avoiding virtual address reuse and clever alignment. This is useful in long RTL tests which allocate fixed number of surfaces. Resulted in 15% time reduction.
- **Fermi GPU Graphics Context Switch** Fermi added a new microcode engine to do this. Helped the component lead find areas to better pipeline save/load operations so they can happen in parallel. Implemented the initial version of context switch code. This was latter owned by a different engineer.

Education

MS Computer Science, Worcester Polytechnic Institute, MA [2003 Aug ~ 2005 May]

- **Thesis**: Remote Execution for 3D Graphics. A distributed 3D Rendering pipeline (RMESA) to offload floating point intensive operations to a cluster.
- Recipient of **WPI Institute Fellowship Award** for outstanding research work.

BS Computer Science, University of Mumbai [1999 July ~ 2003 May]

Skills

C/Java/x86 Assembly. Familiar with Linux/Solaris/Windows systems programming and Linux/Solaris kernel VM subsystems, dtrace. Asynchronous programming, threads, efficient locking, data structures.

Publications

Side Projects (Java/C)

- **Fair spin lock**: Ticket locks on x86 implemented using lock add limit througput by disallowing all but one thread from contesting for lock. Modified this to allow a range of ticket owners to contest for lock instead of a single ticket owner.
- **Hierarchical Spinlock** (Distributed Spinlock) separate groups of threads use a node lock. Central lock is arbitrated between node locks. When local node has no contenders it parks it and other nodes can steal lock ownership using proxy threads. Reduces cacheline traffic substantially.
- **Concurrent Radix Tree** A modified radix tree with a modulo based Bloom Filter that uses optimistic loops around nodes instead of pessimistic locks.
